Gap Penalties

The score at a position can also factor in a penalty for introducing gaps (i. e., not going from i, j to $i-1, j-1$).

Gap penalties are often of linear form:

$$\text{GAP} = a + bN$$

GAP is the gap penalty

a = cost of opening a gap

b = cost of extending the gap by one (affine)

N = length of the gap

(Here assume $b=0$, $a=1/2$, so $\text{GAP} = 1/2$ regardless of length.)

ATGCAAAT

ATG-AAAAT .5

ATG--AAAT .5 + (1)b [b=.1]

ATG---AAT .5 + (2)(.1) = .7

Step 2 -- Computing the Sum

Matrix with Gaps

```

  cell(R,C)                                { Old value, either 1 or 0 }
  + Max[
    cell(R+1, C+1),                        { Diagonally Down, no gaps }
    cells(R+1, C+2 to C_max) - GAP,        { Down a row, making col. gap }
    cells(R+2 to R_max, C+1) - GAP        { Down a col., making row gap }
  ]

Key Idea in Dynamic Programming

- ◇ The best alignment that ends at a given pair of positions (i and j) in the 2 sequences is the score of the best alignment previous to this position PLUS the score for aligning those two positions.
- ◇ An Example Below
 - Aligning R to K does not affect alignment of previous N-terminal residues. Once this is done it is **fixed**. Then go on to align D to E.
 - How could this be violated?
Aligning R to K changes best alignment in box.

Where do matrices come from?

- + —> More likely than random
- 0 —> At random base rate
- —> Less likely than random

- 1 Manually align protein structures
(or, more risky, sequences)
- 2 Look at frequency of a.a. substitutions
at structurally constant sites. -- i.e. pair i-j
exchanges

- 3 Compute log-odds

$$S(\text{aa-1}, \text{aa-2}) = \log_2 (\text{freq}(O) / \text{freq}(E))$$

O = observed exchanges,

E = expected exchanges

- odds = freq(observed) / freq(expected)
- $S_{ij} = \log \text{ odds}$
- $\text{freq}(\text{expected}) = f(i) * f(j)$
= is the chance of getting amino acid i in a
column and then having it change to j
- e.g. A-R pair observed only a tenth as often as
expected

Modifications for Local Alignment

- 1 The scoring system uses negative scores for mismatches
 - 2 The minimum score for at a matrix element is zero
 - 3 Find the best score anywhere in the matrix (not just last column or row)
- These three changes cause the algorithm to seek high scoring subsequences, which are not penalized for their global effects (mod. 1), which don't include areas of poor match (mod. 2), and which can occur anywhere (mod. 3)
