

Biomedical Data Science (GersteinLab.org/courses/452)

Multiple Sequences (23m4)

Last edit in spring '23. Similar to 22m4 & 2021's M4 [which has a video]. Additions include slides on agglomerative clustering [slide 5] & HMMs [slide 28], compared to M4. Also, some slide deletions related to low-complexity regions & mult. seq. alignment issues

Multiple Sequence Alignment Topics

- Multiple Sequence Alignment
- Motifs
 - Fast identification methods
- Profile Patterns
 - Refinement via EM
 - Gibbs Sampling
- HMMs
- Applications
 - Protein Domain databases
 - Regression vs expression

- One of the most essential tools in molecular biology

It is widely used in:

- Phylogenetic analysis
- Prediction of protein secondary/tertiary structure
- Finding diagnostic patterns to characterize protein families
- Detecting new homologies between new genes and established sequence families

Multiple Sequence Alignments

- Practically useful methods only since 1987
- Before 1987 they were constructed by hand
- The basic problem: no dynamic programming approach can be used
- First useful approach by D. Sankoff (1987) based on phylogenetics

Progressive Multiple Alignments

(quick, simplified overview)

- Most multiple alignments based on this approach
- Initial guess for a phylogenetic tree based on pairwise alignments
- Built progressively starting with most closely related sequences
- Follows branching order in tree
- Sufficiently fast
- Sensitive
- Algorithmically heuristic, no mathematical property associated with the alignment
- Biologically sound, it is common to derive alignments which are impossible to improve by eye

(adapted from Sonhammer et al. (1997). "Pfam," Proteins 28:405-20)

↓ (using Euclidean Dist.)

Agglomerative Clustering

- Ex. From Wikipedia
- Suppose we have merged the two closest elements b and c, we now have the following clusters $\{a\}$, $\{b, c\}$, $\{d\}$, $\{e\}$ and $\{f\}$, and want to merge them further. To do that, we need to take the distance between $\{a\}$ and $\{b, c\}$, and therefore define the distance between two clusters.

Clustering approaches for multiple sequence alignment

- Clustal uses average linkage clustering

◇ also called UPGMA

Unweighted Pair Group Method with Arithmetic mean

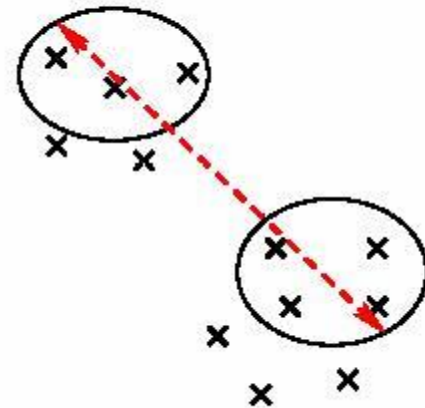

- Simple linkage

- Average linkage

- Complete linkage

<http://compbio.pbworks.com/f/linkages.JPG>

Problems in Multiple Alignment

Domain Problem

Match 3

Match 2

Match 1

Query

Local Minimum Problem

- Stems from greedy nature of alignment (mistakes made early in alignment cannot be corrected later)

Multiple Alignment

MOTIFS

Prosites Pattern -- EGF like pattern

A sequence of about thirty to forty amino-acid residues long found in the sequence of epidermal growth factor (EGF) has been shown [1 to 6] to be present, in a more or less conserved form, in a large number of other, mostly animal proteins. The proteins currently known to contain one or more copies of an EGF-like pattern are listed below.

- Bone morphogenic protein 1 (BMP-1), a protein which induces cartilage and bone formation.
- Caenorhabditis elegans developmental proteins lin-12 (13 copies) and glp-1 (10 copies).
- Calcium-dependent serine proteinase (CASP) which degrades the extracellular matrix proteins type ...
- Cell surface antigen 114/A10 (3 copies).
- Cell surface glycoprotein complex transmembrane subunit .
- Coagulation associated proteins C, Z (2 copies) and S (4 copies).
- Coagulation factors VII, IX, X and XII (2 copies).
- Complement C1r/C1s components (1 copy).
- Complement-activating component of Ra-reactive factor (RARF) (1 copy).
- Complement components C6, C7, C8 alpha and beta chains, and C9 (1 copy).
- Epidermal growth factor precursor (7-9 copies).

'C': conserved cysteine involved in a disulfide bond.

'G': often conserved glycine

'a': often conserved aromatic amino acid

'*': position of both patterns.

'x': any residue

-Consensus pattern: C-x-C-x(5)-G-x(2)-C

[The 3 C's are involved in disulfide bonds]

2 common applications for motif analysis

- Given a collection of binding sites (or protein sequences with binding motifs), develop a representation of those sites that can be used to search new sites and reliably predict where additional binding sites occur.
- Given a set of sequences known to contain binding sites for a common factor, but not knowing where the sites are, discover the location of the sites in each sequence and a representation of the protein.

Profiles formula for position M(p,a)

M(p,a) = chance of finding amino acid a at position p

$M_{simp}(p,a)$ = number of times a occurs at p divided by number of sequences

However, what if don't have many sequences in alignment? $M_{simp}(p,a)$ might be biased. Zeros for rare amino acids. Thus:

$$M_{cplx}(p,a) = \sum_{b=1 \text{ to } 20} M_{simp}(p,b) \times Y(b,a)$$

Y(b,a): Dayhoff matrix for a and b amino acids

$$S(p,a) \sim \sum_{a=1 \text{ to } 20} M_{simp}(p,a) \ln M_{simp}(p,a)$$

Scanning for Motifs with PWMs

Position Weight Matrices define an additive scheme for scoring sequence. Often, the weights are simply log likelihood ratios of observing a nucleotide in a binding site relative to genomic background. Sequences are scanned by scoring every site, on both the forward and reverse complement strands, and identifying matches as shown in the schematic below:

A particular site is evaluated by adding up the entries from the scoring matrix at each position, and comparing the sum to a match threshold. For log ratio PWMs, an empirically chosen threshold of 60% of the maximum positive score has been used by Harbison et al. and is approximately equal to cutoffs determined by the principled cross-validated method presented in Maclsaac et al. More sophisticated algorithms developed specifically for motif scanning are described briefly in Figure 3.

Ψ-Blast

Parameters: overall threshold, inclusion threshold, interations

Gapped BLAST and PSI-BLAST: a new generation of protein database search programs

Stephen F. Altschul*, Thomas L. Madden, Alejandro A. Schaffer¹, Jinghui Zhang, Zheng Zhang², Webb Miller² and David J. Lipman

National Center for Biotechnology Information, Bethesda, MD 20894, USA, ¹Laboratory of Molecular Biology, National Institutes of Health, Bethesda, MD 20894, USA, ²Department of Engineering, Pennsylvania State University, University Park, PA 16802, USA

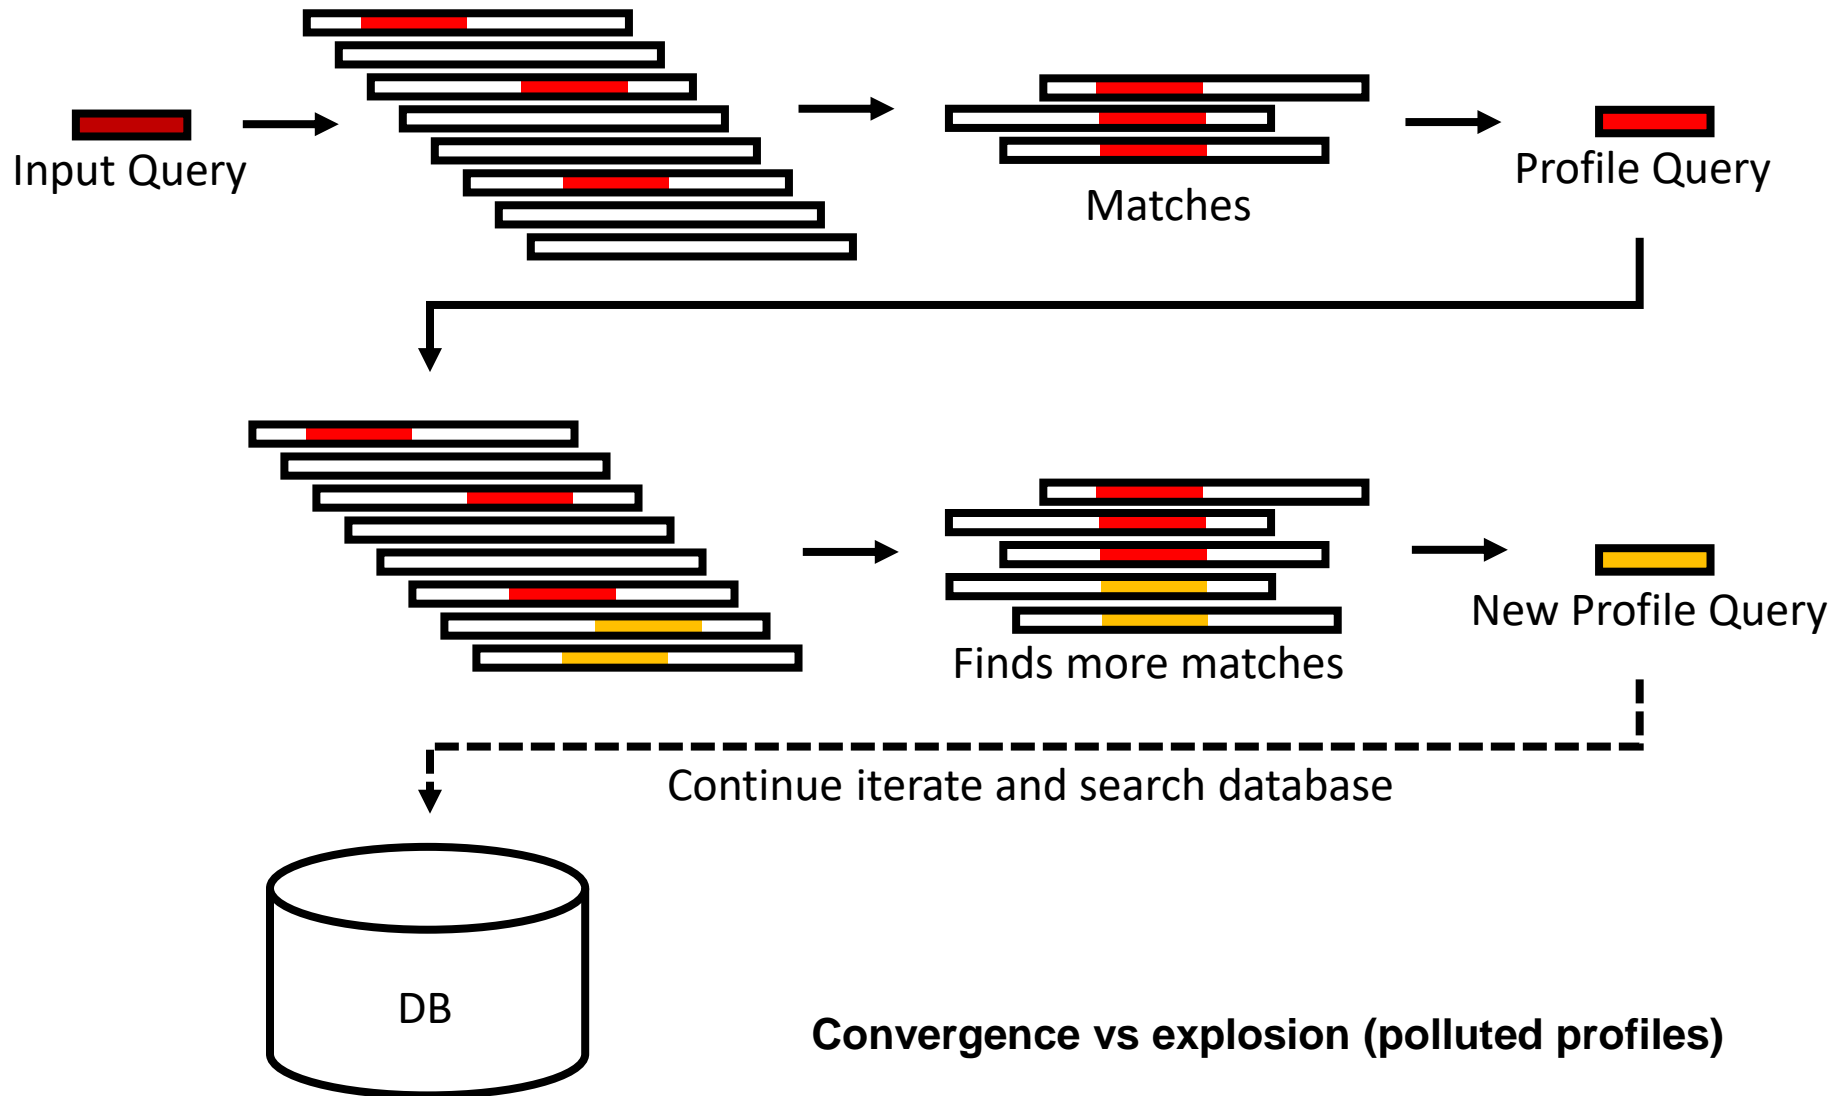

Received June 20, 1997; Revised and Accepted August 1, 1997

ABSTRACT

The BLAST programs are widely used to search protein and DNA databases for sequence similarities. For protein comparisons, we have developed a new algorithm, Gapped BLAST, which uses a heuristic search of a database for high-scoring segments of a query sequence. This algorithm is faster than the standard BLAST algorithm and produces more accurate results. We have also developed a new algorithm, PSI-BLAST, which uses an iterative search of a database for high-scoring segments of a query sequence. This algorithm is faster than the standard BLAST algorithm and produces more accurate results. We describe the definition, algorithmic and statistical properties of these programs.

PSI-BLAST (Position-Specific Iterative Basic Local Alignment Search Tool)

Multiple Alignment: Probabilistic Approaches for Determining PWMs

- Expectation Maximization: Search the PWM space randomly
- Gibbs sampling: Search sequence space randomly.

Expectation-Maximization (EM) algorithm

- Used in statistics for finding maximum likelihood estimates of parameters in probabilistic models, where the model depends on unobserved latent variables.
 - EM alternates between performing
 - an expectation (E) step, which computes an expectation of the likelihood by including the latent variables as if they were observed, and
 - a maximization (M) step, which computes the maximum likelihood estimates of the parameters by maximizing the expected likelihood found on the E step.
 - The parameters found on the M step are then used to begin another E step, and the process is repeated.
1. Guess an initial weight matrix
 2. Use weight matrix to predict instances in the input sequences
 3. Use instances to predict a weight matrix
 4. Repeat 2 [E-step] & 3 [M-step] until satisfied.

[Also Adapted from C Bruce, CBB752 '09]

Multiple Alignment

Gibbs Sampling

Initialization

- Step 1: Randomly guess an instance s_i from each of t input sequences $\{S_1, \dots, S_t\}$.

Gibbs sampler

- Steps 2 & 3 (search):
 - Throw away an instance s_i : remaining $(t - 1)$ instances define weight matrix.
 - Weight matrix defines instance probability at each position of input string S_i
 - Pick new s_i according to probability distribution (not necessarily always the s_i giving the highest prob.)
- Return highest-scoring motif seen

Comparison

- Both EM and Gibbs sampling involve iterating over two steps
- Convergence:
 - EM converges when the PSSM stops changing.
 - Gibbs sampling runs until you ask it to stop.
- Solution:
 - EM may not find the motif with the highest score.
 - Gibbs sampling will provably find the motif with the highest score, if you let it run long enough.

Multiple Alignment

HMMs

Hidden Markov Model:

- a composition of finite number of states,
- each corresponding to a column in a multiple alignment
- each state emits symbols, according to symbol-emission probabilities

HMMs

Starting from an initial state, a sequence of symbols is generated by moving from state to state until an end state is reached.

state sequence (hidden):

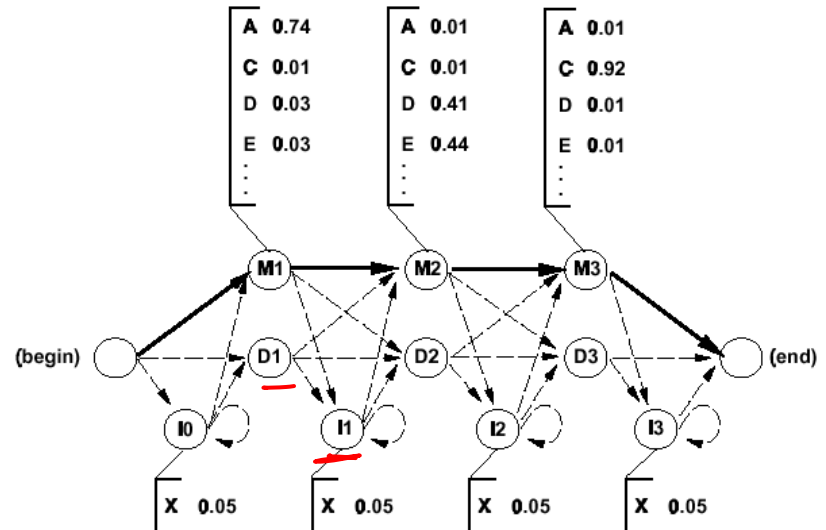

... (1) (1) (1) (1) (1) (2) (2) (2) (2) (1) (1) ...

transitions: ? 0.99 0.99 0.99 0.99 0.01 0.9 0.9 0.9 0.1 0.99

symbol sequence (observable):

... A T C A A G G C G A T ...

emissions: 0.4 0.4 0.1 0.4 0.4 0.5 0.5 0.4 0.5 0.4 0.4

Algorithms

Probability of a path through the model

Viterbi maximizes for seq

Forward sums of all possible paths

Forward Algorithm – finds probability P that a model λ emits a given sequence O by summing over all paths that emit the sequence the probability of that path

Viterbi Algorithm – finds the most probable path through the model for a given sequence
(both usually just boil down to simple applications of dynamic programming)
